

Email Campaign Experiment

Decision memo for a historical 64,000-customer, three-arm randomized email campaign.

Decision

Advance **Mens E-Mail** as the candidate for a monitored rollout, provided incremental contribution clears the send-cost threshold and unsubscribe and deliverability guardrails are acceptable.

Evidence

ITT contrast	Visit lift	Conversion lift	Mean spend lift
Mens E-Mail vs No E-Mail	+7.66 pp [7.00, 8.32]	+0.68 pp [0.50, 0.86]	+0.77 [0.49, 1.05]
Womens E-Mail vs No E-Mail	+4.52 pp [3.89, 5.16]	+0.31 pp [0.15, 0.47]	+0.42 [0.17, 0.68]
Mens vs Womens E-Mail	+3.14 pp [2.43, 3.84]	+0.37 pp [0.17, 0.56]	+0.35 [0.03, 0.66]

All brackets are large-sample 95% confidence intervals. The six email-versus-control tests were Holm-adjusted as one primary family; all remained significant. The Mens-versus-Womens tests were a separately declared secondary family. Maximum baseline |SMD| was 0.016.

Interpretation

Both email treatments increased visits, conversions, and mean spend relative to control in this experiment. Mens E-Mail had the larger observed effect on all three outcomes. The single planned newbie interaction check did not support a targeting rule.

Launch condition and limitations

The data contain revenue, not profit, and omit campaign cost, gross margin, unsubscribe risk, and deliverability. If gross-margin rate is m and marginal send cost is c , the conservative lower confidence bound supports positive short-run contribution only when $c < m \times 0.485$ per assigned customer. Retain a randomized holdout during rollout and pre-register the contribution metric and customer-experience guardrails.

Method: intention-to-treat differences in means with unpooled standard errors. Public data: [MineThatData E-Mail Analytics Challenge](#). Raw data are not redistributed.
